Num of flowers Bloom

Given that an 2 matrix of variable rows and 2 sized columnned . Column 1 represent when the flower is bloomed and column 2 represent when the flower is faded. And 2nd array is when people visited and people[i] represent time when they visited.

We've to return an array of same size as people with value i.e how many flowers were bloomed when that people visited.

ex: $\left[[1, 6], [3, 7], [9, 12], [4, 13] \right] = \text{flower}$

A worksheet for counting hibiscus flowers. The first row contains 13 boxes, each containing a hibiscus flower. The second row contains 13 boxes, each containing a number from 0 to 12. Below the boxes are four large numbers: 1, 2, 2, and 2.

people :- 2, 3, 7, 11

$$\text{Ans} \stackrel{?}{=} [1, 2, 2, 2] = \text{ans}$$

How we can solve the question?

i) Brute force :

If we look carefully the flowers matrix column 1 min element represent what is the starting time of the visit can start and similarly the column 2 max represent the ending time of the visiting time.

So, min (column 1)
max (Column 2) → give us the range of visiting time

Look the example above :-

1	6
3	7
9	12
4	13

$$\min = 1$$
$$\max = 13$$

1	2	3	4	5	6	7	8	9	10	11	12	13
0	1	2	3	3	3	2	1	2	2	2	2	2

Ans:- Now, we've a range of time and if we calculated the no. of flower bloomed at that time.

fun(flower, people) {

 size of flower = flower.size();

 size of people = people.size();

 min^o = min(flower)

 max = max(flower)

 map<int> mp;

 for(int i = min^o to max ; i++) {

 mp[i] = 0;

 }

 for(i = 0 to size of flower ; i++) {

 for(j = flower[i][0] to flower[i][1] ; j++) {

 mp[j] += j;

 }

 }

 ans[];

 for(i = 0 to size of people)

 ans[i] = mp[people[i]]

 return ans;

}

Time complexity : $(N \times (\text{max-min}))$

$O(\text{people.size})$

we can
optimise this
part

* In the above we are iterating over a loop or a range and incrementing its value by one. but if we observe something

1 3 9 4 → sort

6 7 12 13

✓ ✓ ✓ 4
1 3 9 9

if people visit

Let say between 7.

✓ ✓
6 7 12 13
|

$$3-1=2$$

All the flowers before 7 will be bloomed and in the

end time array all the flower at or before 7 will be faded.

In start time if we found an upper bound it's working because the will start blooming at x and for $x+1$ it'll bloom.

In end time the if we found the lower bound because the flower will be faded till that x .

```
for (i = 0 to sizeof people ; i++) {  
    bloomed = upper_bound (start, people);  
    faded = lower_bound (end, people);  
    res[i] = bloomed - faded;  
}  
return res;
```
